

# File Formats

DSCI 551

Wensheng Wu

# File Formats

- Specify what information bits in file encode
- Example: text file
  - String of characters with particular **encoding** scheme, e.g., ASCII and Unicode
  - E.g., TXT, HTML, JSON, XML
- Others: xls, ppt, pdf, jpg, gif, mp3, png, etc.

# Roadmap

- Character encoding

- ASCII
- Unicode

- JSON (done earlier)

- XML (will talk about it next)

# Code space & points

- Code space
  - A range of numerical values available for encoding characters
  - E.g., 0 to 10FFFF for Unicode, 0 to 7F for ASCII
- Code point
  - A value for a character in a code space
- Unicode code point
  - U+ followed by its hexadecimal value, e.g., U+0058 for capital letter 'X') => u'\u0058'

# Encoding (of code points)

- Code unit: the smallest unit (comprising a number of bits) used to construct an encoding for a code point
  - Code unit for UTF-8: 8-bit
  - UTF-16: 16-bit
- UTF (Unicode Transformation Format) encoding
  - E.g., UTF-8 and UTF-16

# Variable-length encoding

- Characters encoded using codes of different length
- In Unicode, a code point may be represented using multiple code units
  - E.g., 1-4 in UTF-8, 1-2 in UTF-16

# ASCII

- American Standard Code for Information Interchange
- 128 characters: 7-bit code (code points: 0~7F)
  - Digits: 0-9 (0x30 – 0x39)
  - Uppercase letters: A-Z (0x41 – 0x5A)
  - Lowercase letters: a-z (0x61 – 0x7A)
  - White space (0x20)
  - Punctuation symbols
  - Control characters (e.g., Ctrl-C: 0x03)

1111 = 15 = F

# ASCII

# Unicode

- Unicode supports more characters than ASCII and various codepages
- Unicode separates code points from encoding
  - In contrast to ASCII, where code point = encoding

# Unicode

- Code space is divided into 17 planes
- Each plane = contiguous  $2^{16}$  code points
- Recall that code points range from 0 to 10FFFF

⇒ Total code points =  $17 * 2^{16}$  or 1,114,112  
code points

Note  $2^{16} = 65,536$

# Planes in Unicode

V·T·E

## Unicode planes and used code point ranges

[hide]

# Plane 0: BMP (Basic Multilingual Plane)

Each block represents 256 code points

# UTF-8

- Encoding scheme for Unicode code space
- Code unit = 8 bits
- Variable length
  - Code point may be represented using 1-4 code units

# UTF-8 Design

- ASCII characters use one code unit
  - First bit is zero
- Other Unicode characters use up to 4 units

Number of bytes	Bits for code point	First code point	Last code point	Byte 1	Byte 2	Byte 3	Byte 4
1	7	U+0000	U+007F	0xxxxxxx			
2	11	U+0080	U+07FF	110xxxxx	10xxxxxx		
3	16	U+0800	U+FFFF	1110xxxx	10xxxxxx	10xxxxxx	
4	21	U+10000	U+10FFFF	11110xxx	10xxxxxx	10xxxxxx	10xxxxxx

# UTF-8 Features

- Backward compatibility
  - One byte for ASCII, leading bit of byte is zero
- Clear distinction btw single- vs. multi-byte characters
  - Single-byte/multi-byte: start with 0/1 respectively
- Multiple length
  - a **leading** byte starts with 2 or more 1's, followed by a 0, e.g., '110', '1110', etc.
  - One or more **continuation** bytes all start with '10'

# UTF-8 Features

- Clear indication of code sequence length
  - By # of 1's in leading byte (for multi-byte)
- Self-synchronization
  - Can find start of characters by backing up at most 3 bytes

# Example

- Encode '€' using UTF-8
- Code point = U+20AC
  - 10 0000 1010 1100
- Need 3 bytes in UTF-8

Character		Binary code point	Binary UTF-8	Hexadecimal UTF-8
\$	U+0024	0100100	00100100	24
¢	U+00A2	00010100010	11000010 10100010	C2 A2
€	U+20AC	0010000010101100	11100010 10000010 10101100	E2 82 AC
⌘	U+10348	000010000001101001000	11110000 10010000 10001101 10001000	F0 90 8D 88

# Unicode in Python

```
>>> a = '\u20ac'
```

```
>>> a  
'€'
```

```
>>> e = a.encode('utf-8')
```

```
>>> e  
b'\xe2\x82\xac'
```

```
>>> e.decode('utf-8')
```

```
'€'
```
